- A generalized additive model (GAM) is fitted to each site and year individually
- Excludes data where peak flight period is unrecorded or more than 30% data requires estimation
- For the UK, nearly 40% of monitored 10km grid squares were excluded

Indexing butterfly abundance whilst accounting for missing counts and variability in seasonal pattern

Emily B. Dennis, Stephen N. Freeman, Tom Brereton, David B. Roy

First published:26 March 2013 | https://doi.org/10.1111/2041-210X.12053 (open)

- A GAM is used to estimate a common flight period across sites for each year.
- More robust indices and trends than single-site GAM or linear interpolation
- Greater use of data
- Disadvantage – can be slow when there are lots of data

Summary. At a time of climate change and major loss of biodiversity, it is important to have efficient tools for monitoring populations. In this context, animal abundance indices play an important rôle. In producing indices for invertebrates, it is important to account for variation in counts within seasons. Two new methods for describing seasonal variation in invertebrate counts have recently been proposed; one is nonparametric, using generalized additive models, and the other is parametric, based on stopover models. We present a novel generalized abundance index which encompasses both parametric and nonparametric approaches. It is extremely efficient to compute this index due to the use of concentrated likelihood techniques. This has particular relevance for the analysis of data from long-term extensive monitoring schemes with records for many species and sites, for which existing modeling techniques can be prohibitively time consuming. Performance of the index is demonstrated by several applications to UK Butterfly Monitoring Scheme data. We demonstrate the potential for new insights into both phenology and spatial variation in seasonal patterns from parametric modeling and the incorporation of covariate dependence, which is relevant for both monitoring and conservation. Associated R code is available on the journal website.

Key words: Butterflies; Citizen science; Concentrated likelihood; Normal mixtures; Phenology; UKBMS.

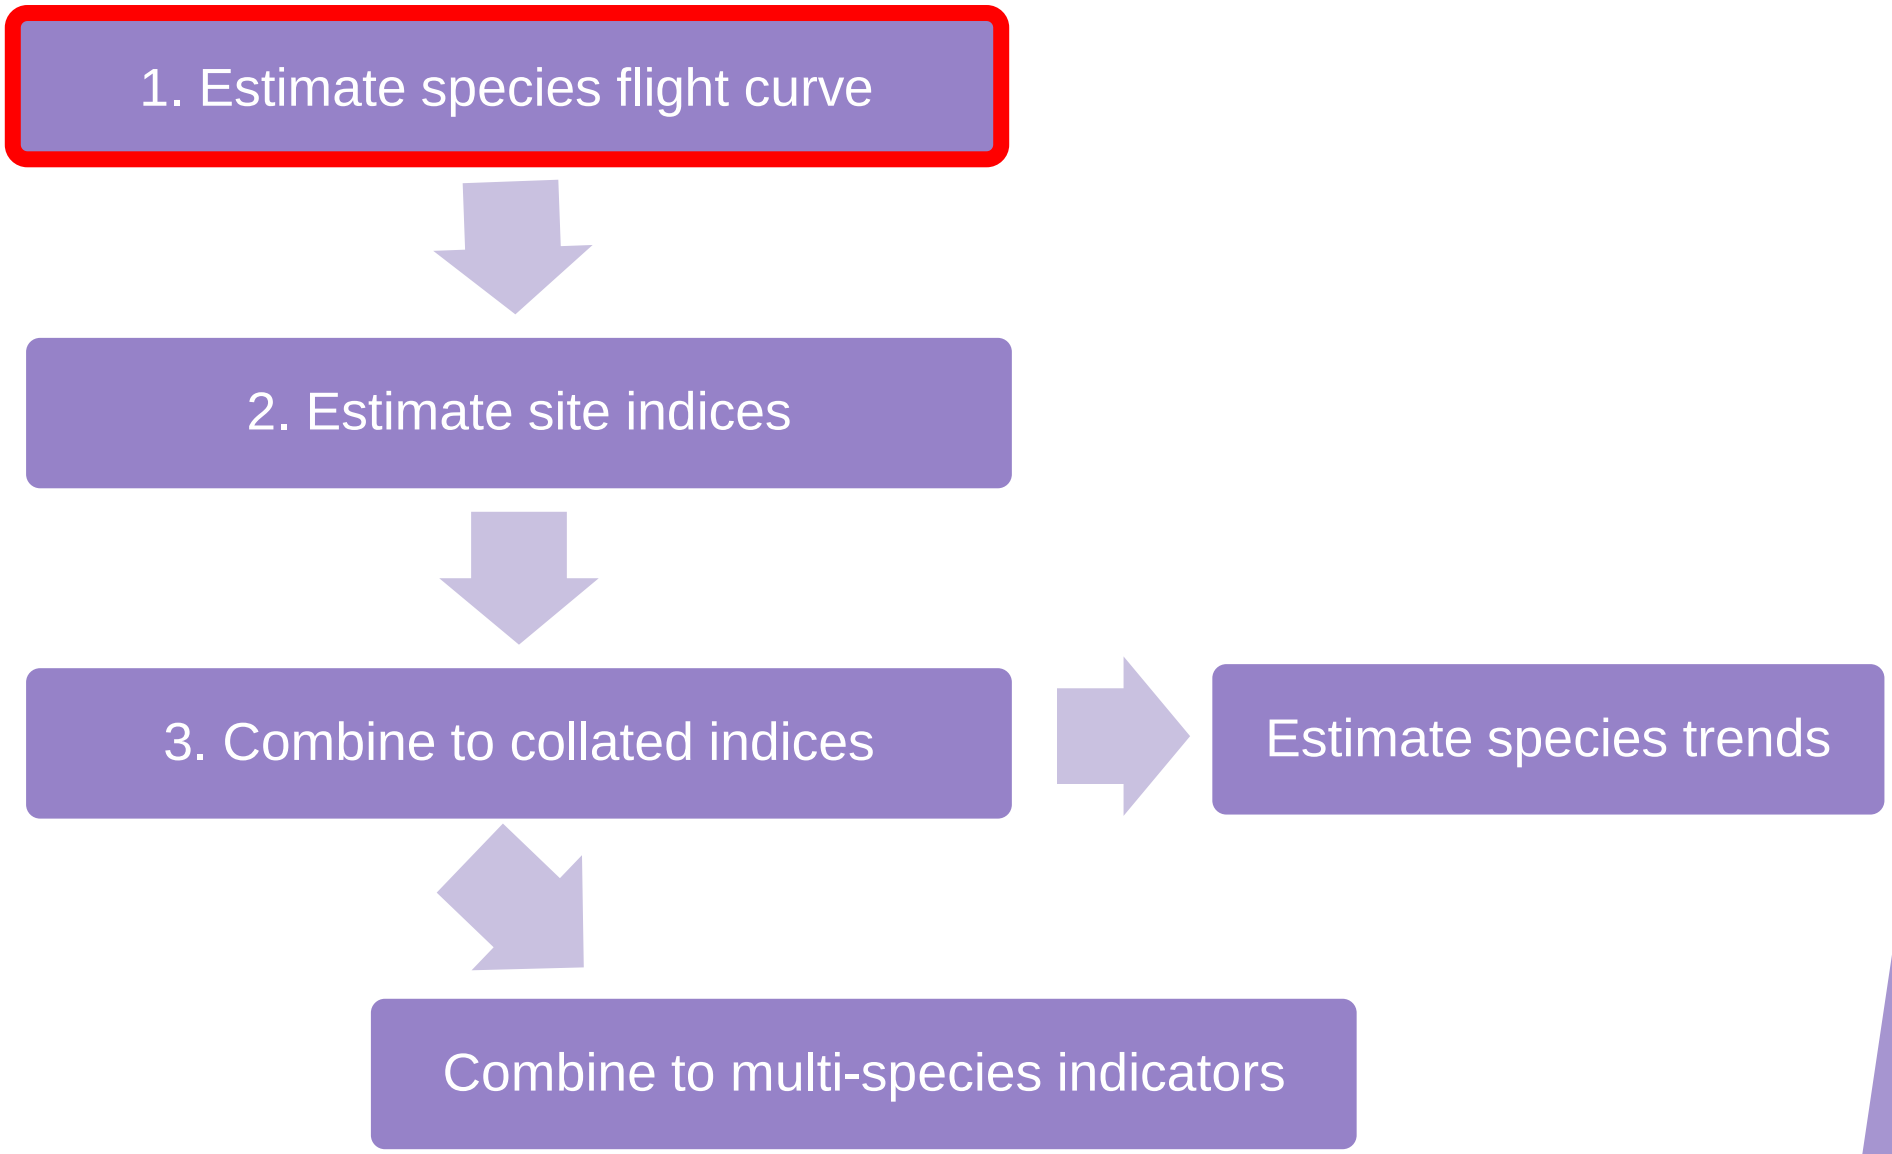
GAI approaches offers three options for describing seasonal variation:

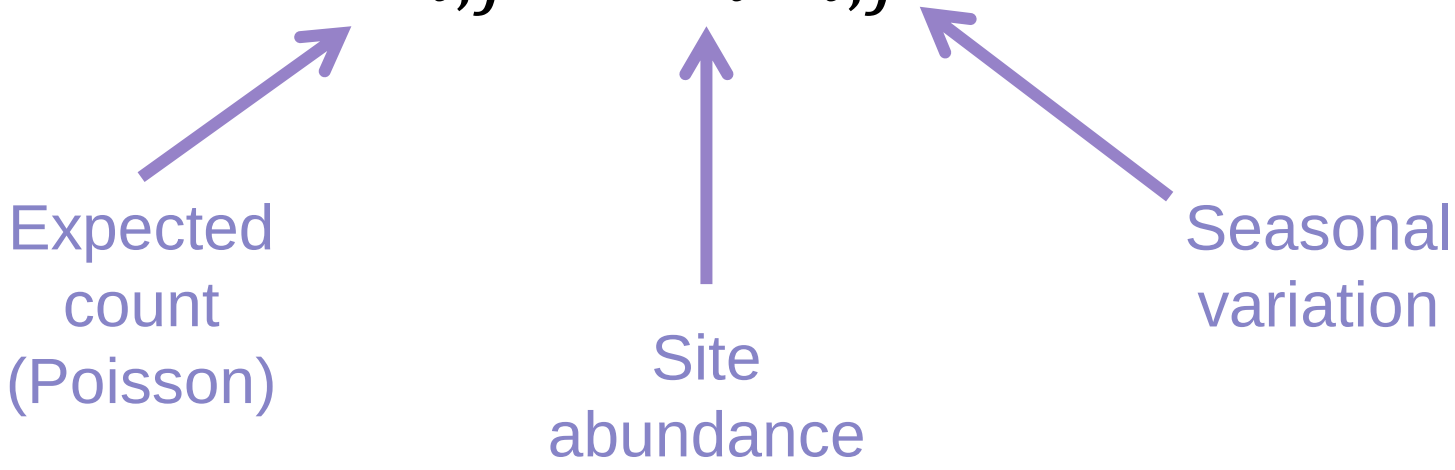
- Flexible spline/GAM across sites each year
- Parametric description for each brood using Normal distributions
  - Phenology estimation, using covariates
- “Stopover model”
  - Mechanistic description with certain assumptions – estimates adult lifespan
  - Relevant paper: **https://doi.org/10.1111/1365-2664.12208** (open)

Overview of modelling steps



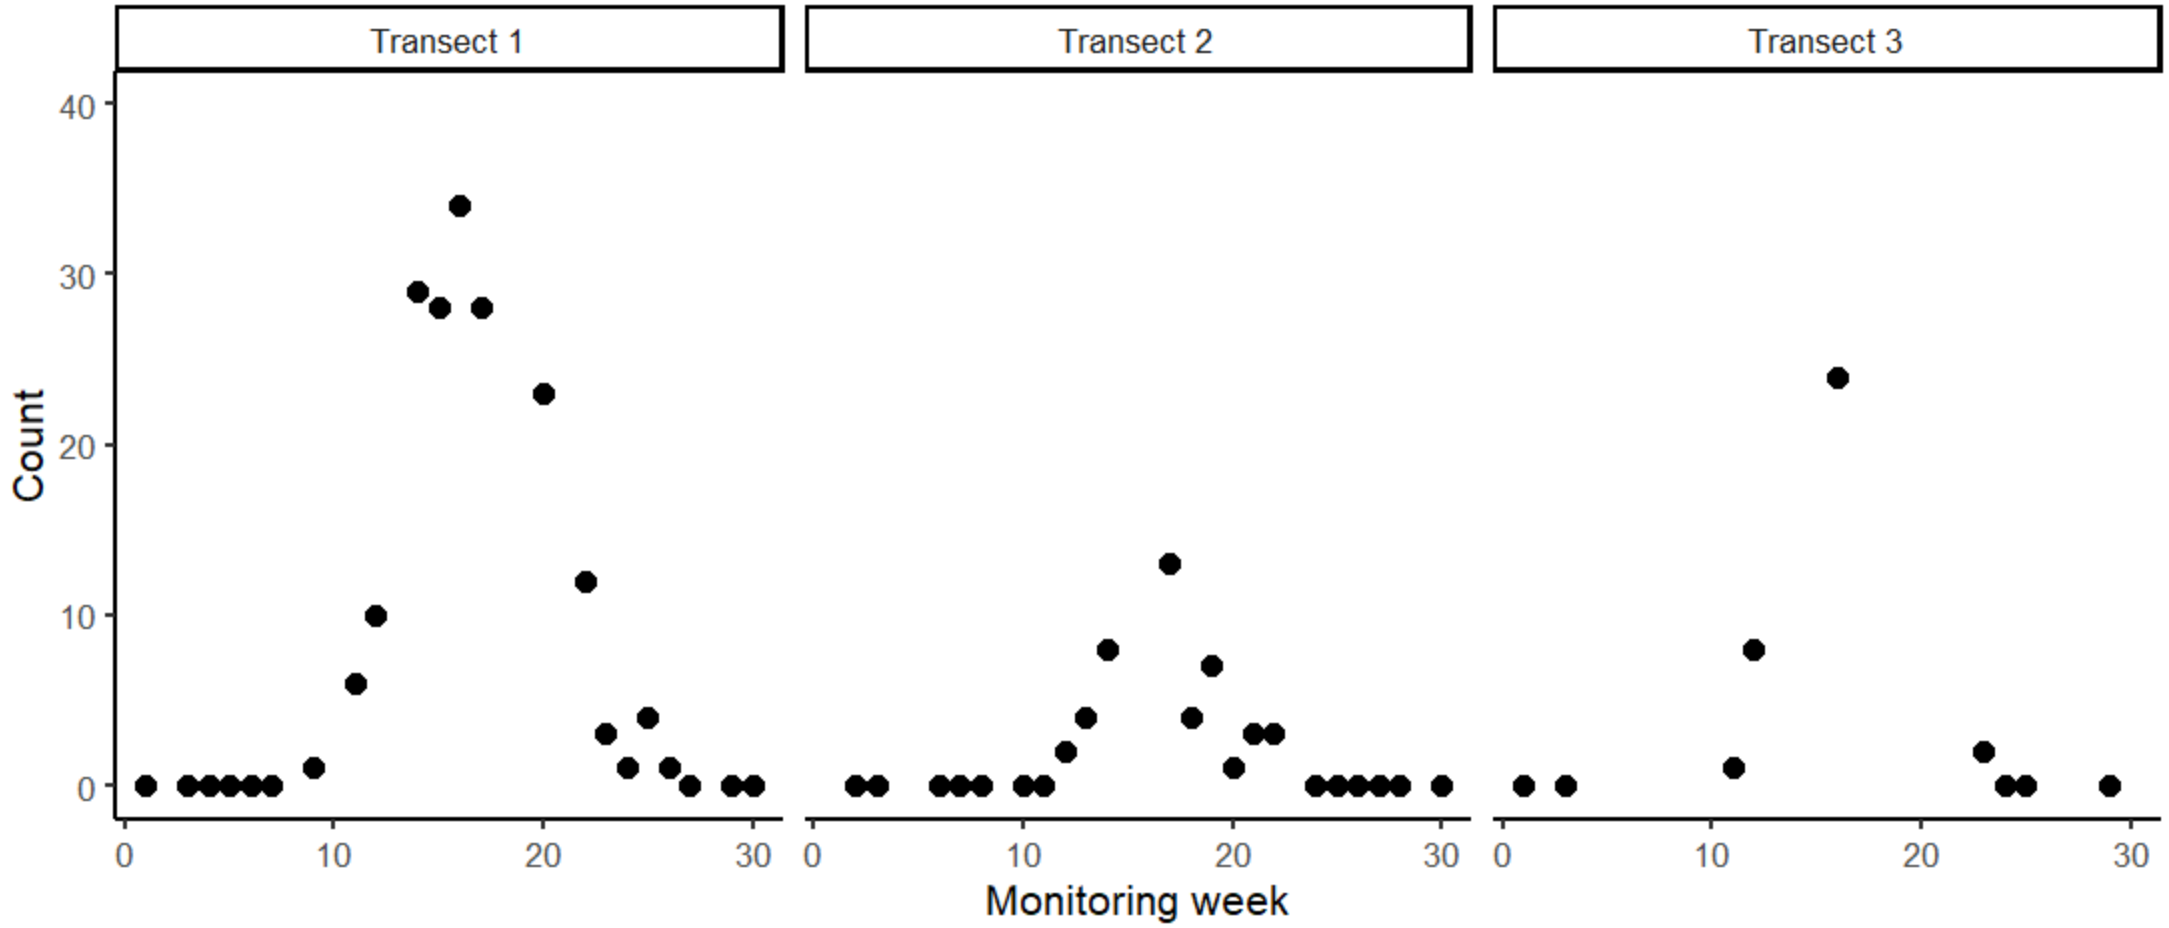
1. Estimate species flight curve

$$\lambda_{i,j} = N_i a_{i,j}$$

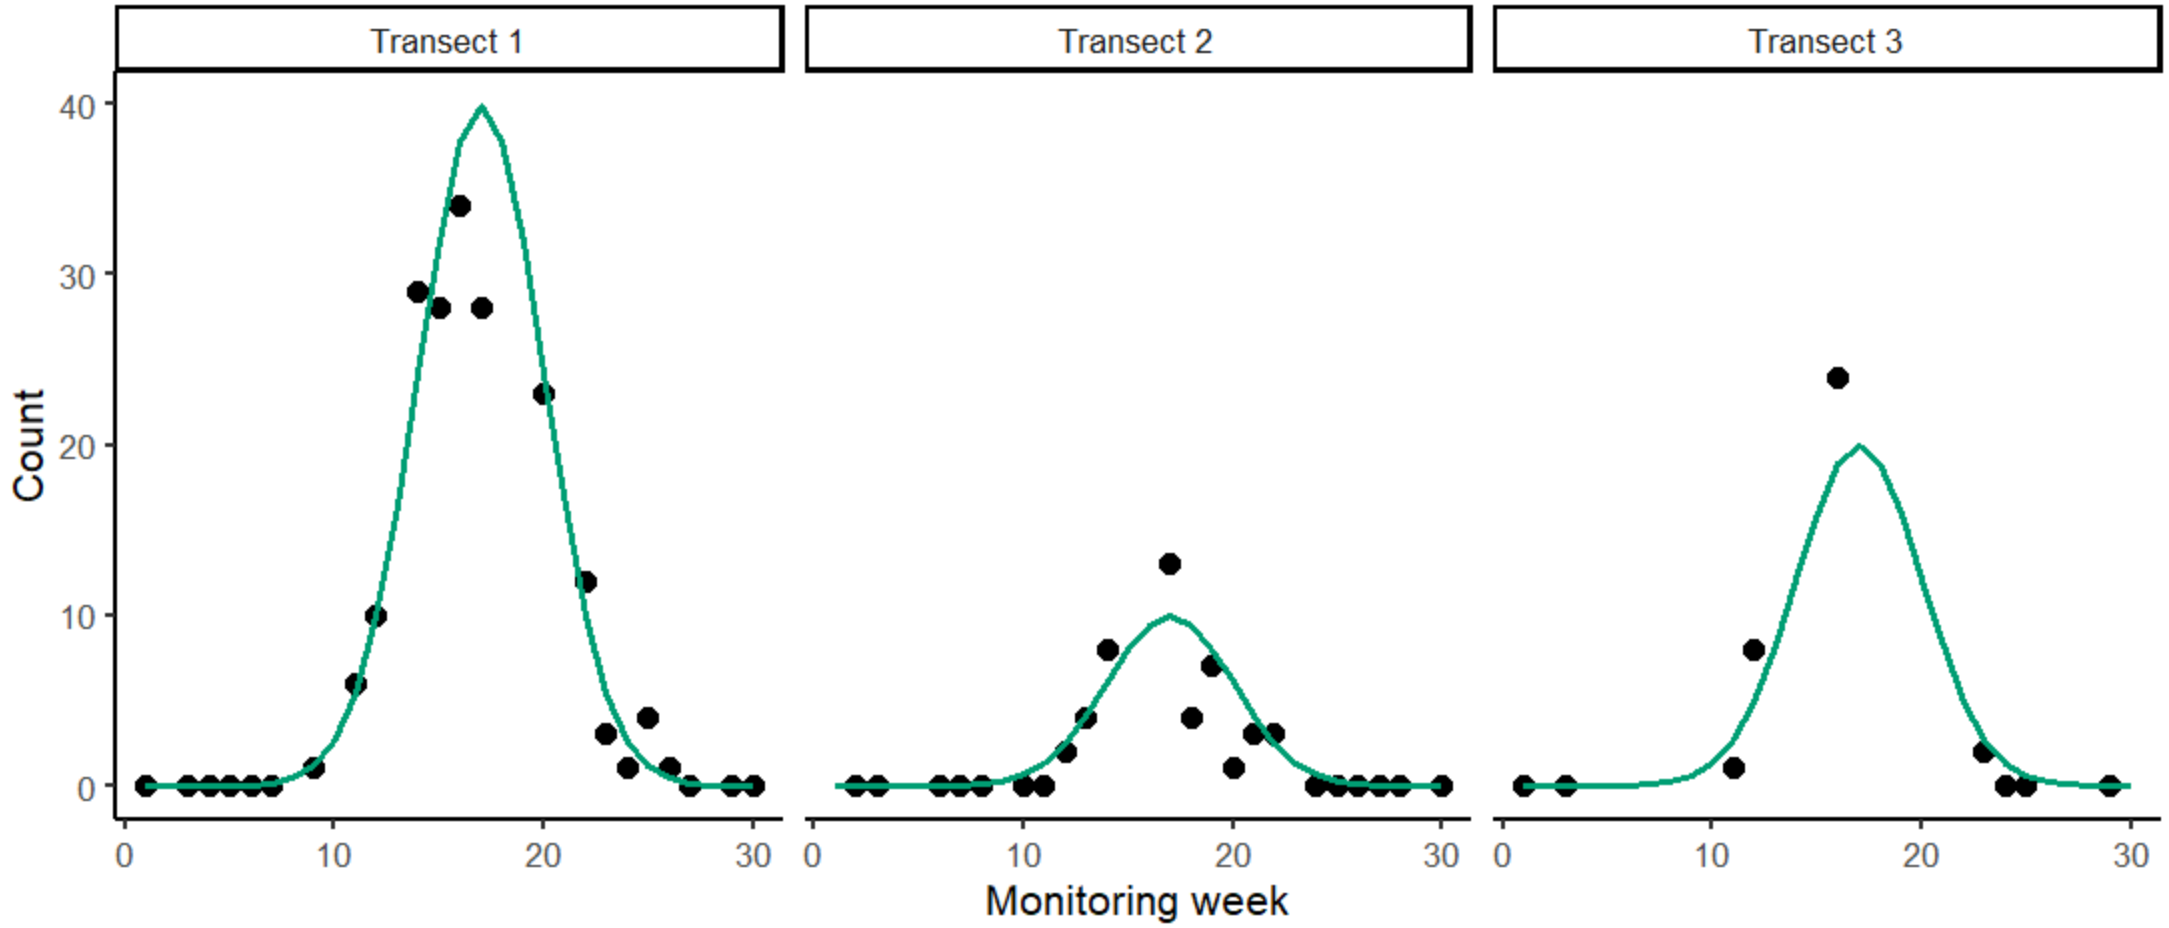


- We use a flexible curve to describe the species flight curve across sites
- The “height” of the curve is reflected by the site effect
- Efficient modelling of the site effects N_i - concentrated likelihood – up to 75 times faster

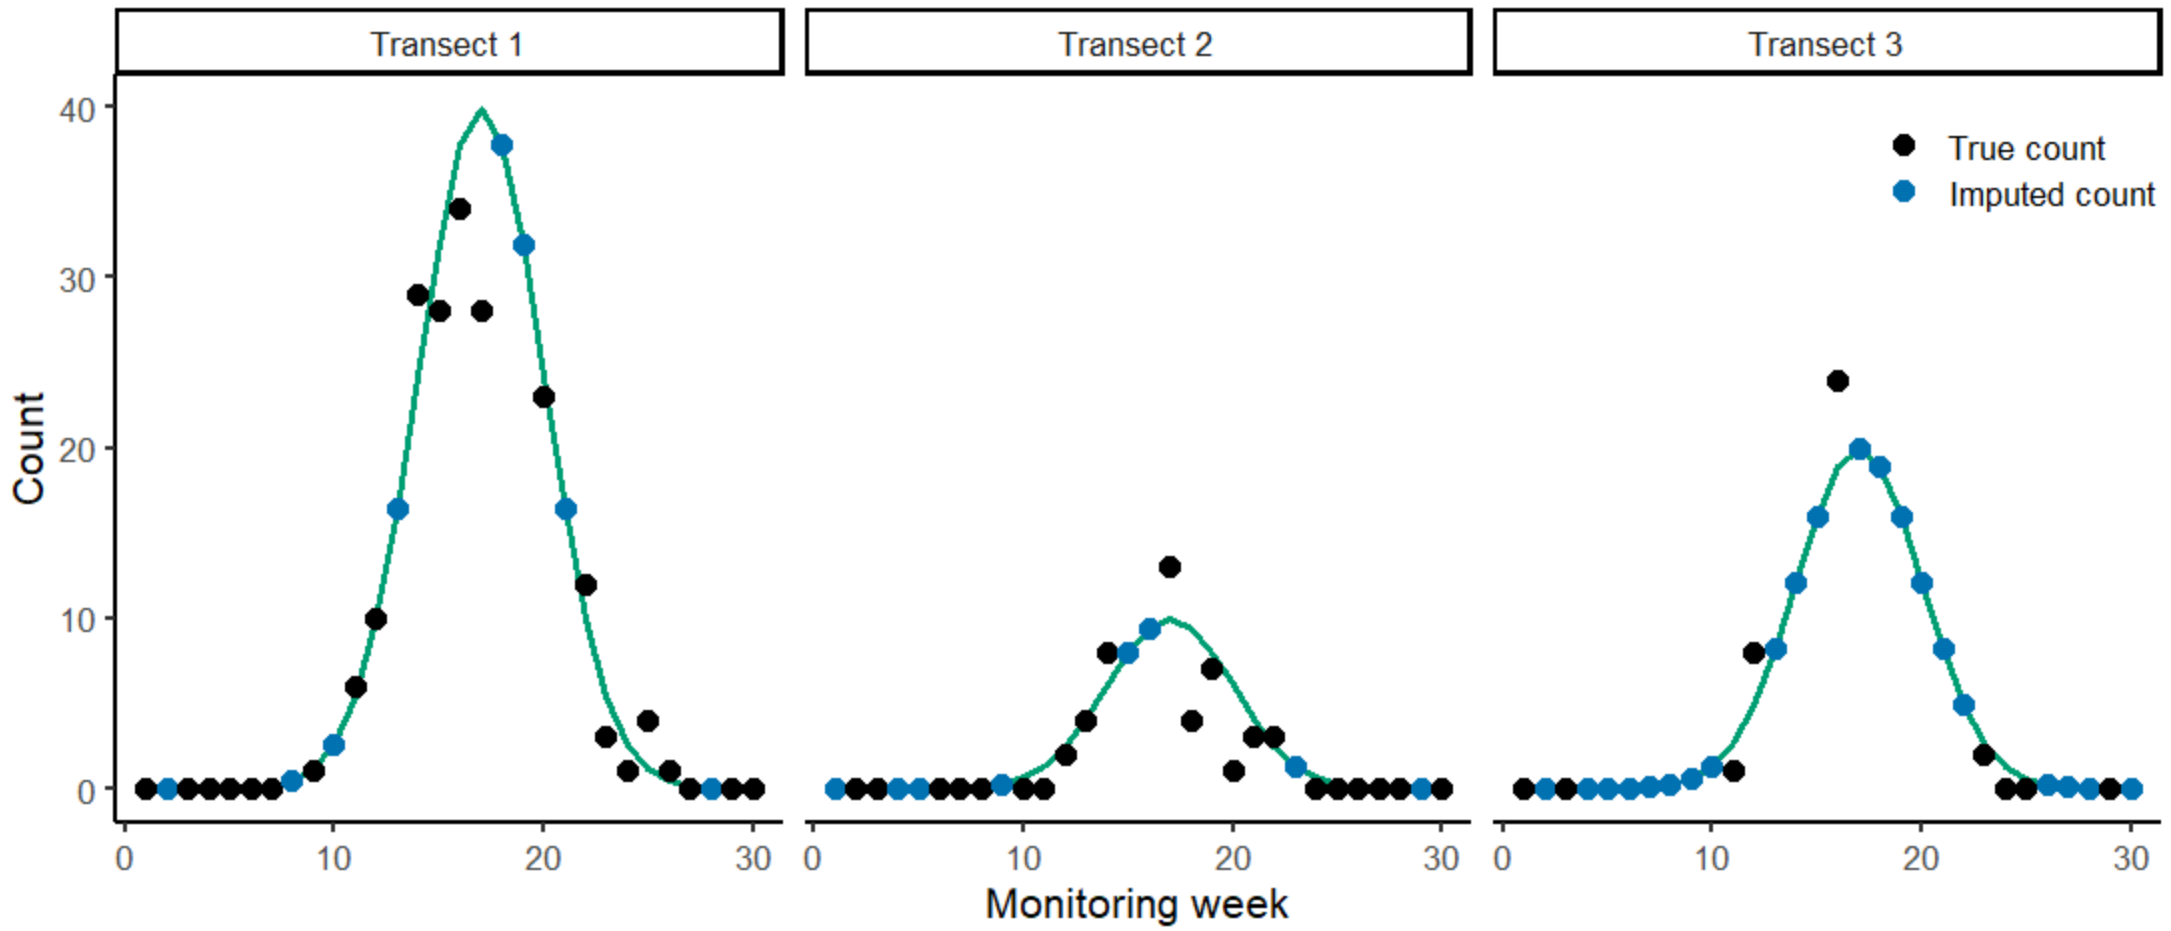
1. Estimate species flight curve



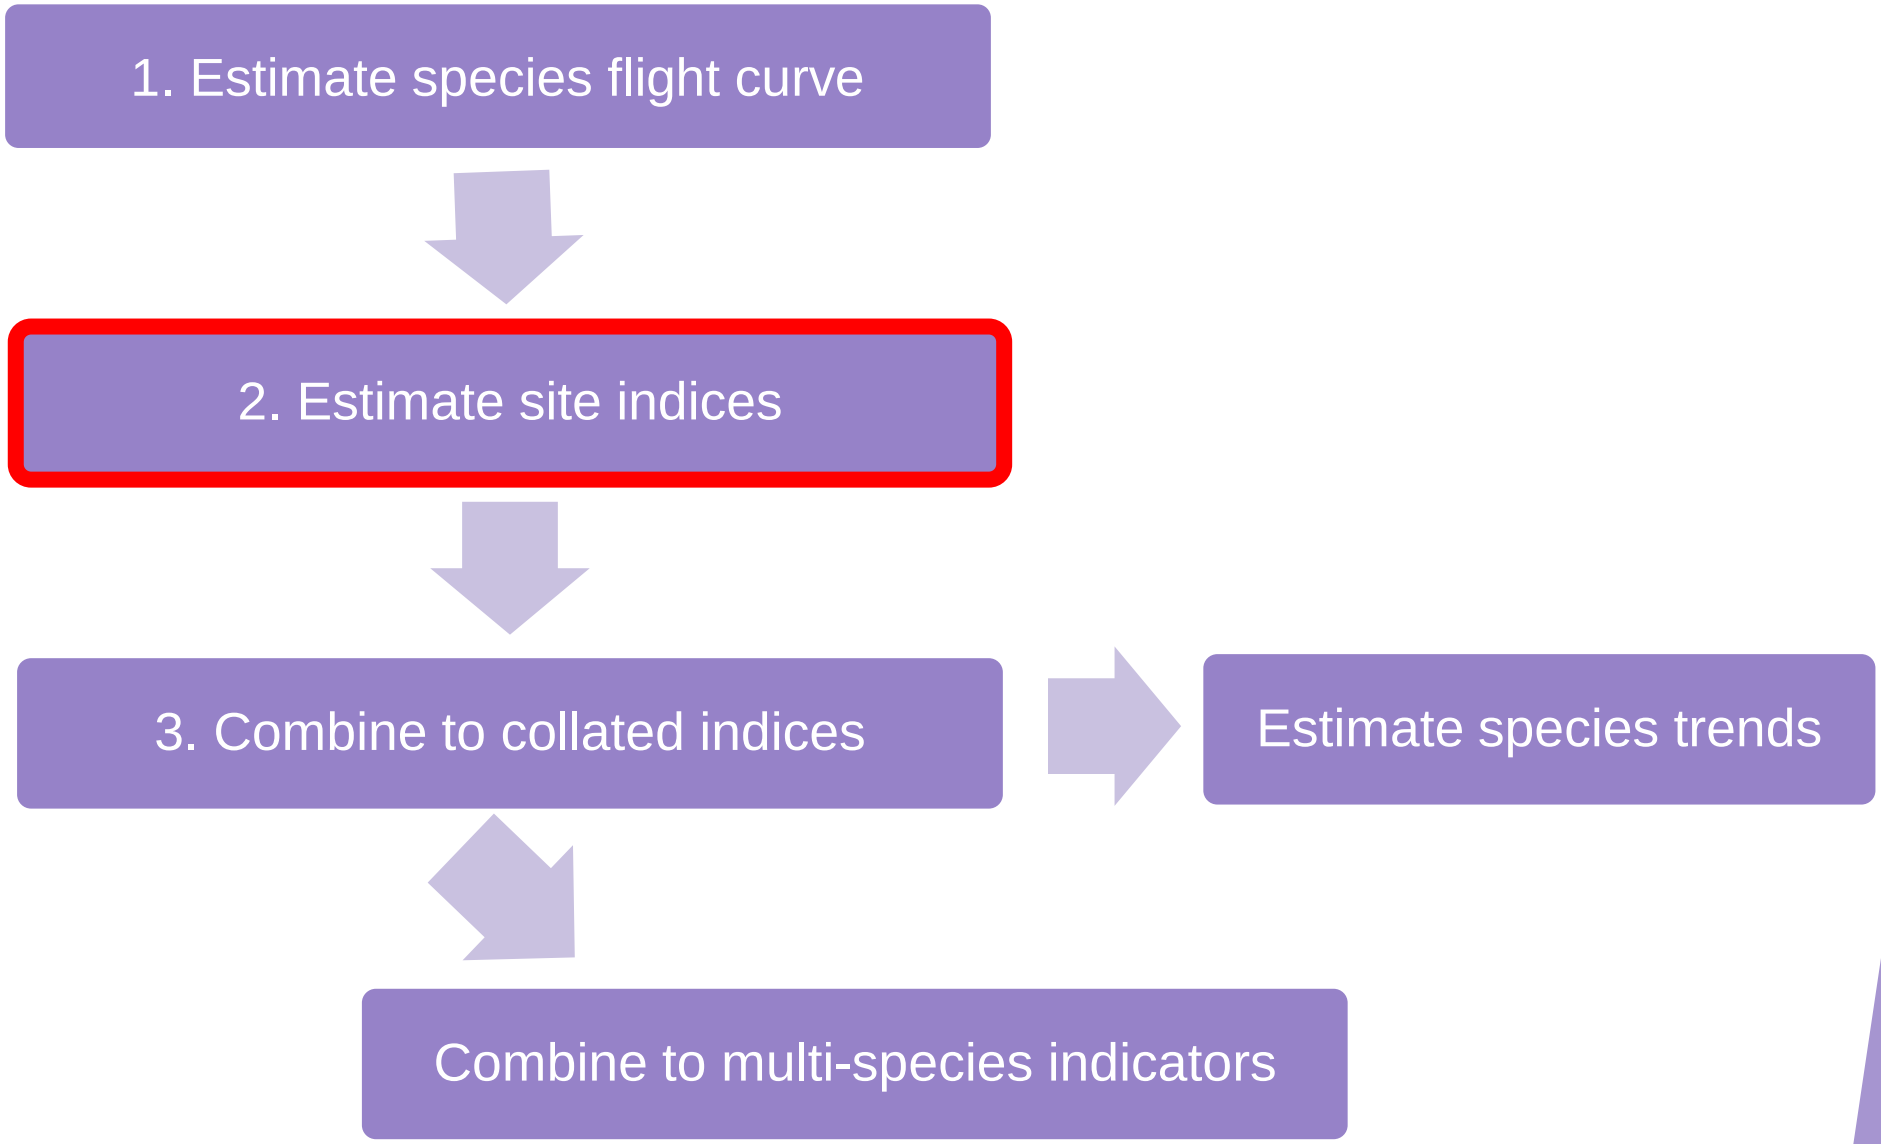
1. Estimate species flight curve



1. Estimate species flight curve



Overview of modelling steps



2. Combine to site indices

For each year:

$$N_i = \frac{\sum_j y_{i,j}}{\sum_j a_{i,j}}$$

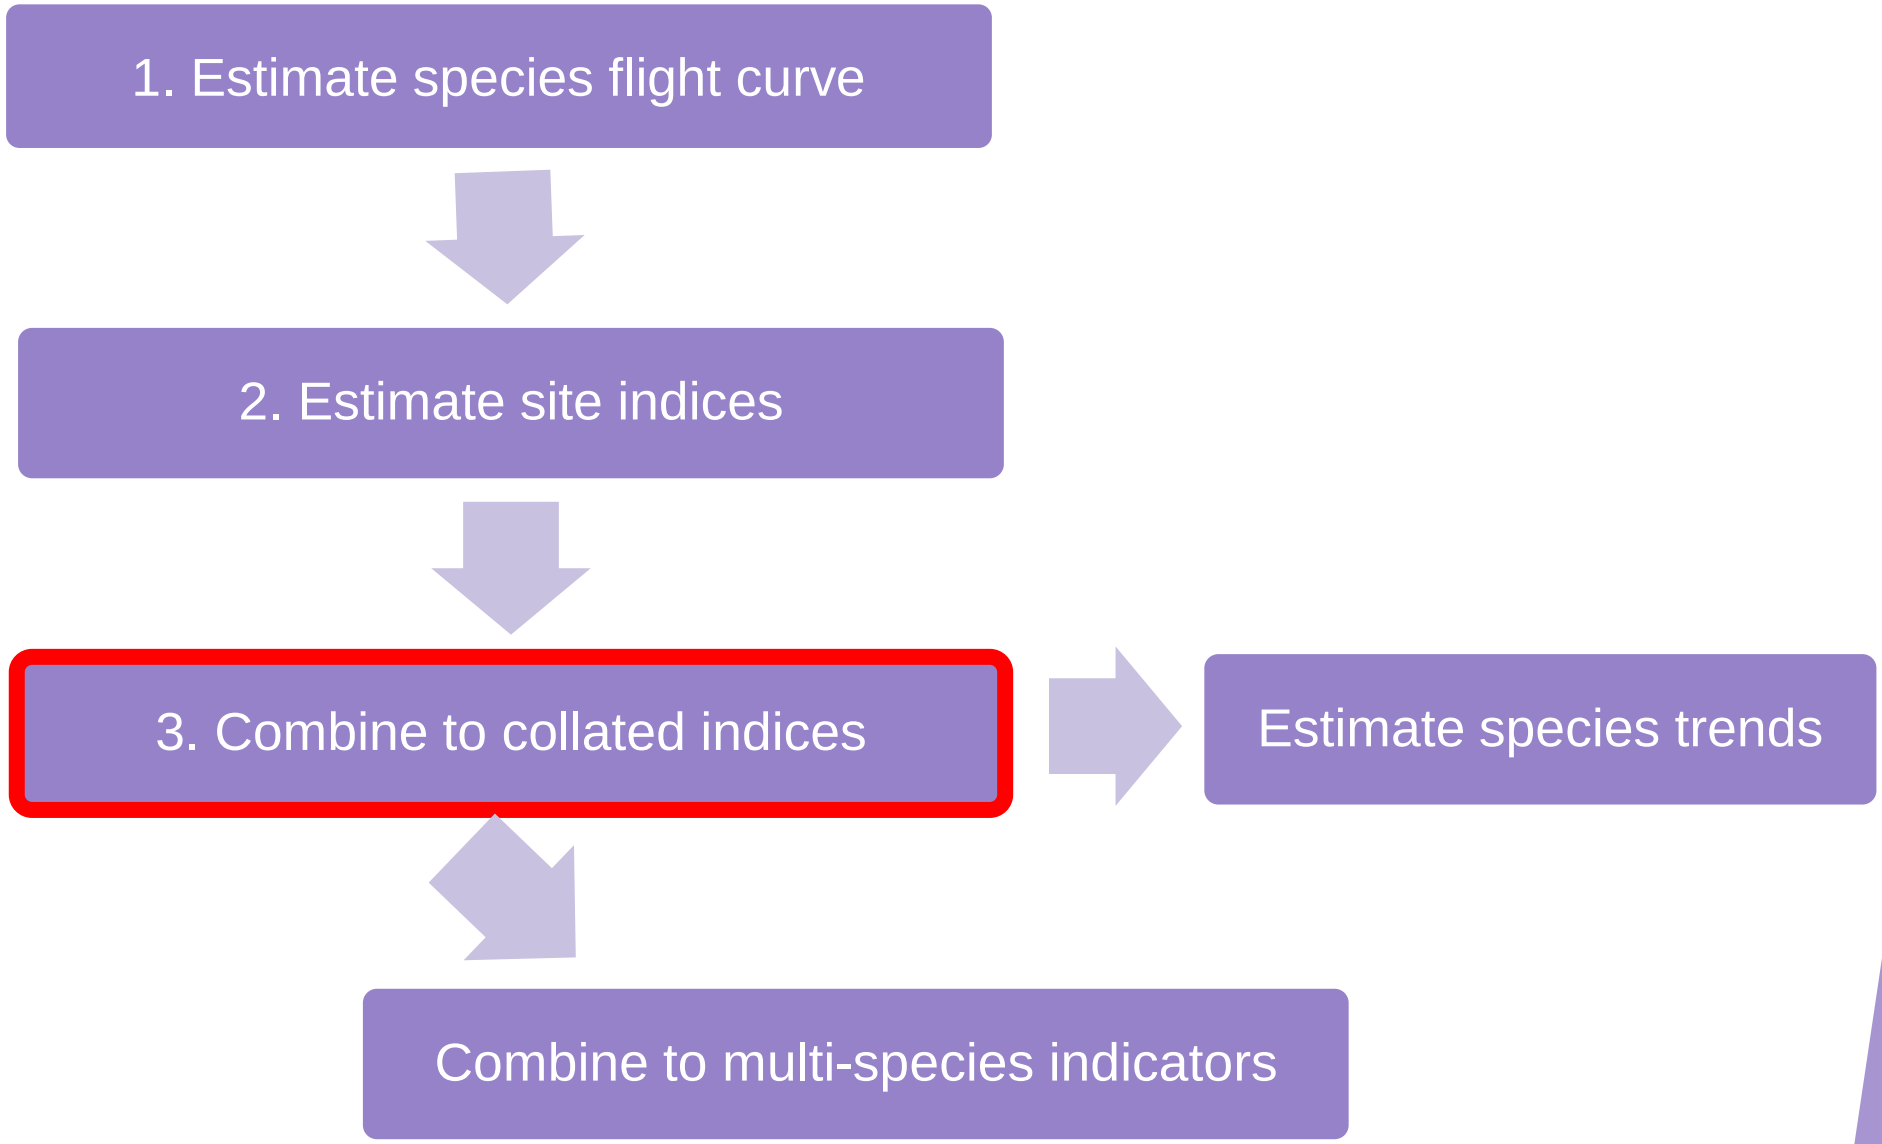
Real counts, summed across visits

Site index

Estimated season pattern, summed across visits

Site indices for each site and year for a given species

Overview of modelling steps



3. Combine to collated indices

We fit a Poisson generalised linear model (GLM):

$$N_{i,k} \sim \alpha_i + \beta_k$$

Site index

Site effect

Year effect

- Also weight by the proportion of the flight curve sampled
  - Well sampled sites contribute more
- We can then obtain expected total butterfly counts/densities
- And convert to collated indices to consider changes in relative abundance over time

Overview of modelling steps

Bootstrapping to measure uncertainty

What is bootstrapping?

Randomly resample from the data (with replacement) many times and apply method to each data resample

Why bootstrap?

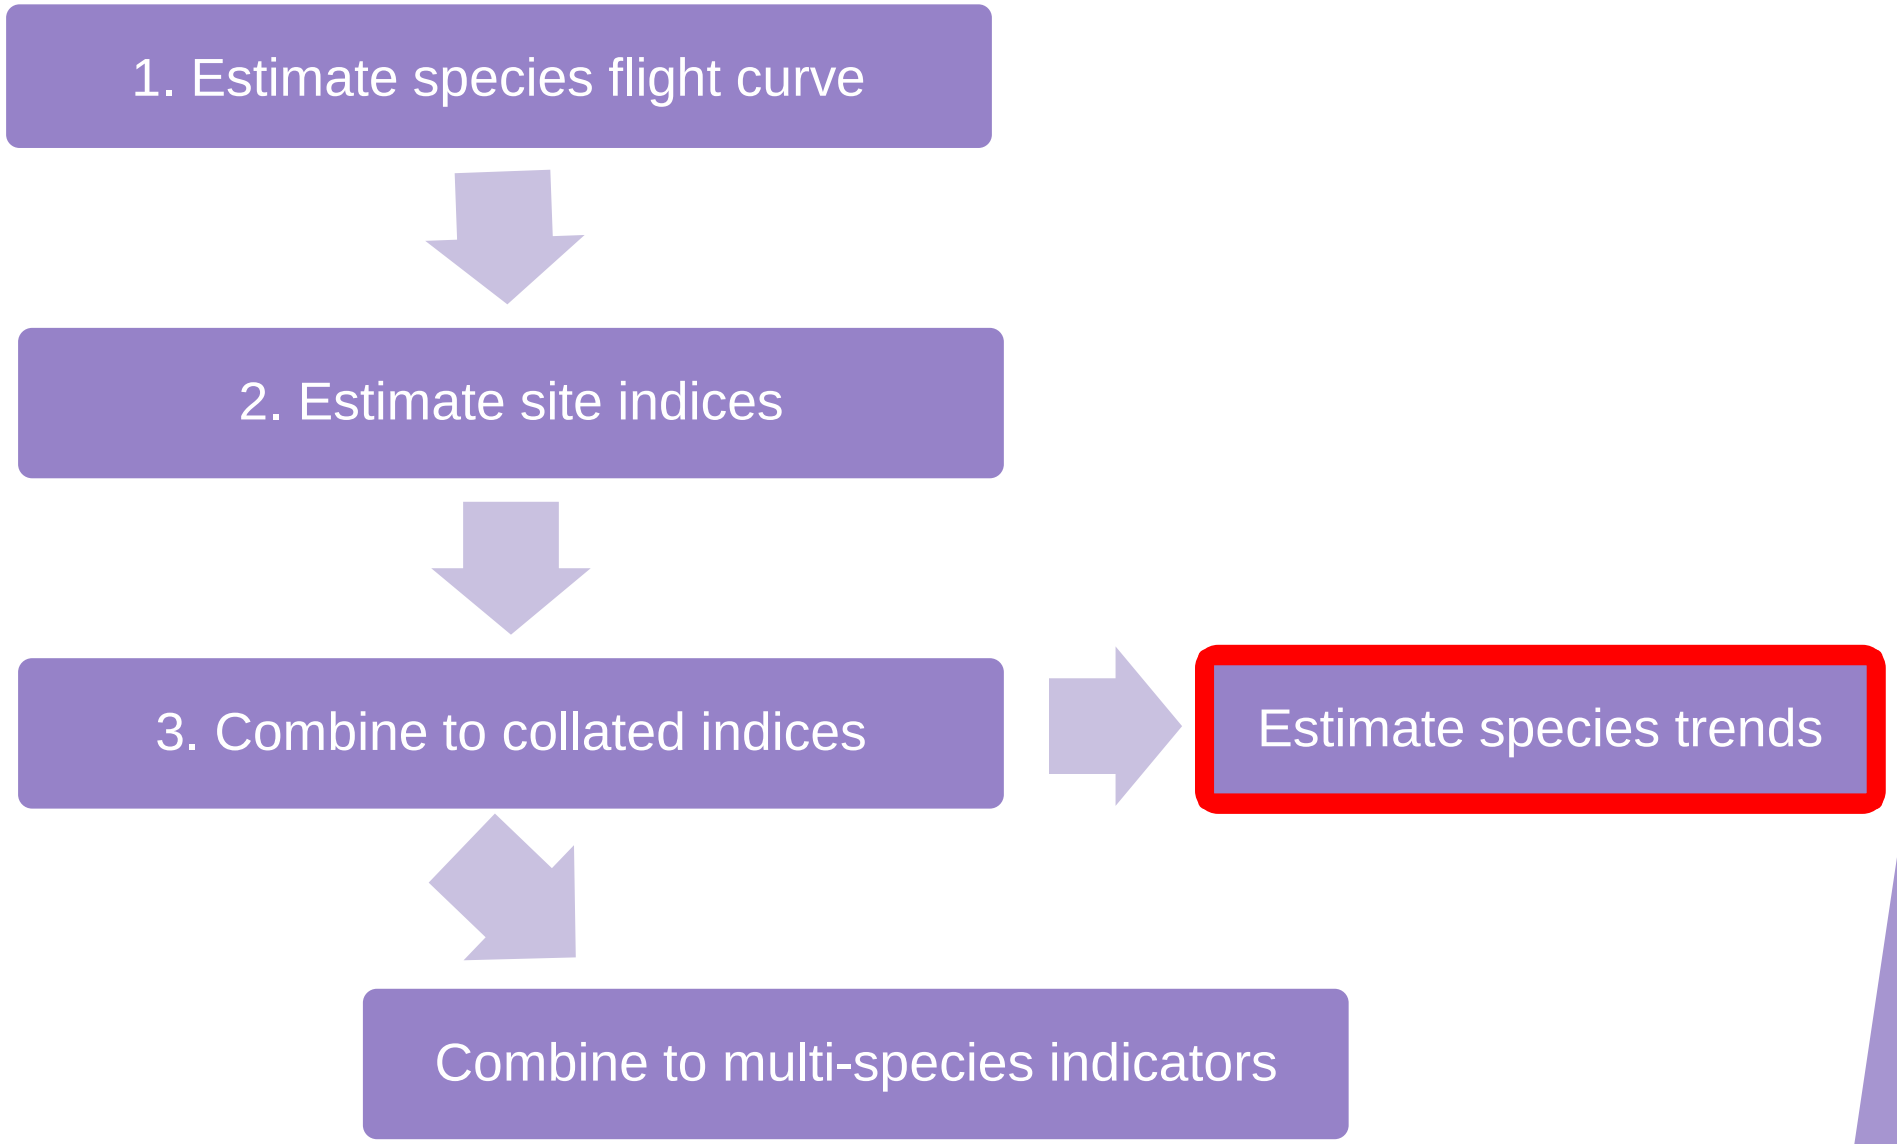
Flexibly account for uncertainty from various sources, including multiple stages of model fitting

How does it work in practice?

1. Resample the data
2. Apply the work flow to each data resample
3. Calculate confidence intervals by taking (95%) quantiles

(e.g. for collated indices, trends, multi-species intervals)

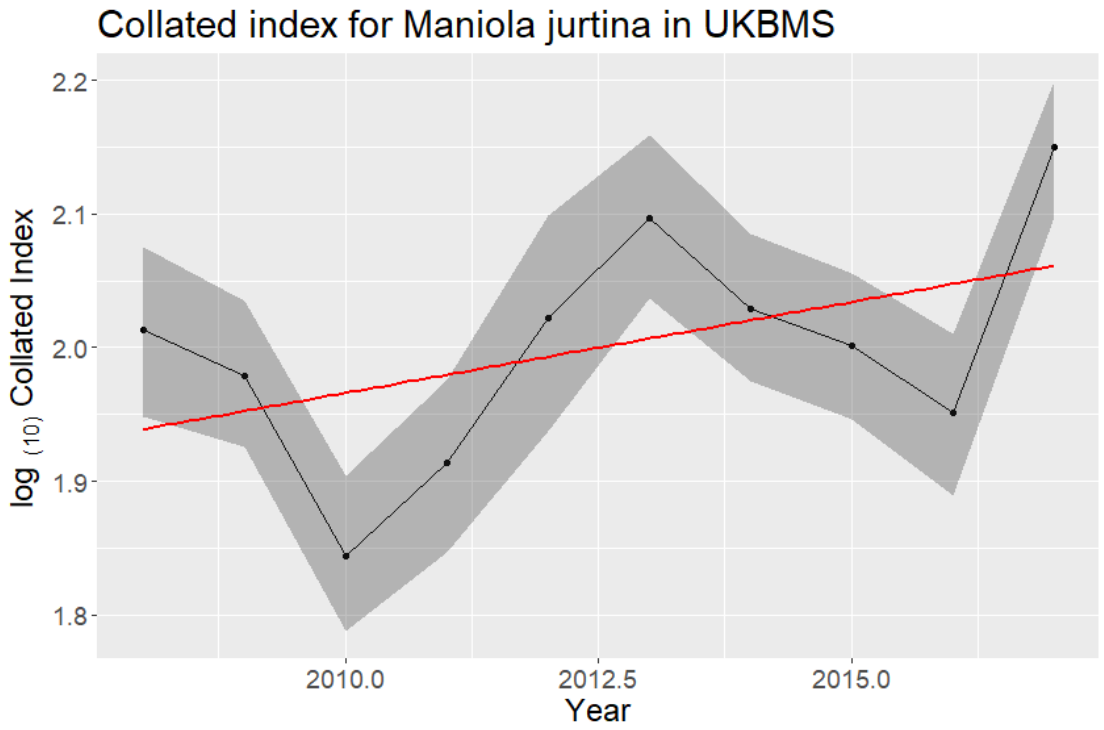
Overview of modelling steps



Calculating species trends

- Fit a linear regression to the species collated index
- Apply to each bootstrap to quantify uncertainty
- Package rtrim:

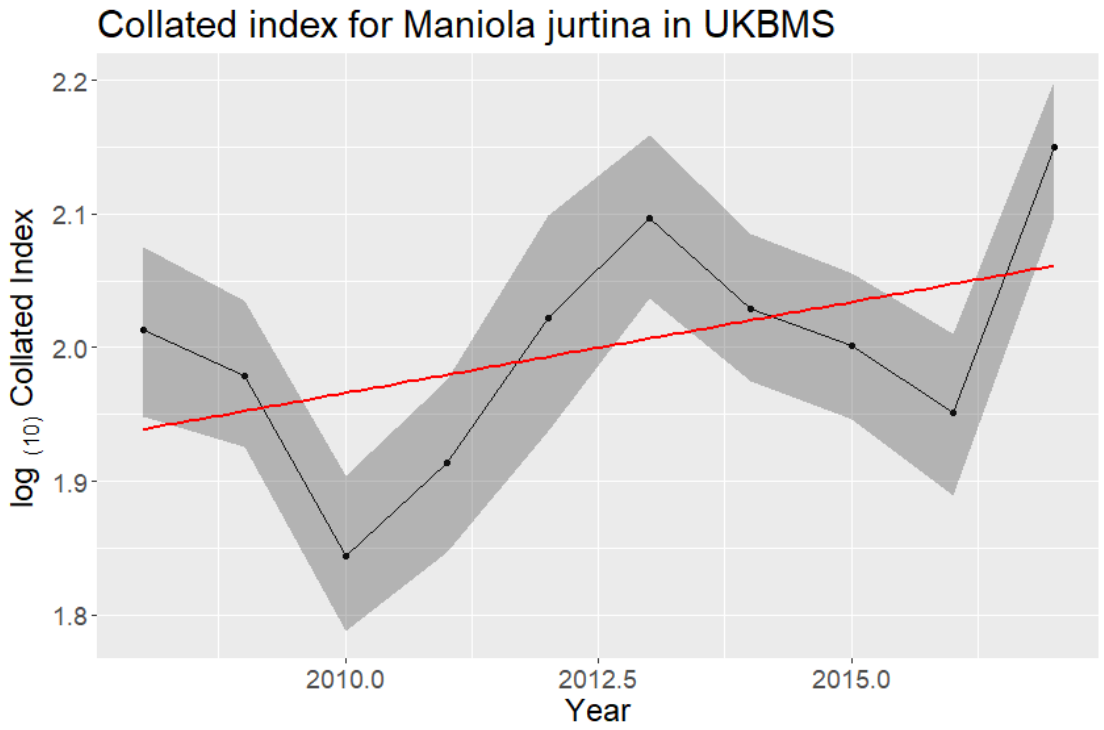
https://cran.r-project.org/web/packages/rtrim/index.html



Date period	Rate of change	% change	Class
2008-2017	1.032 (1.019, 1.045)	32.5%	Moderate increase

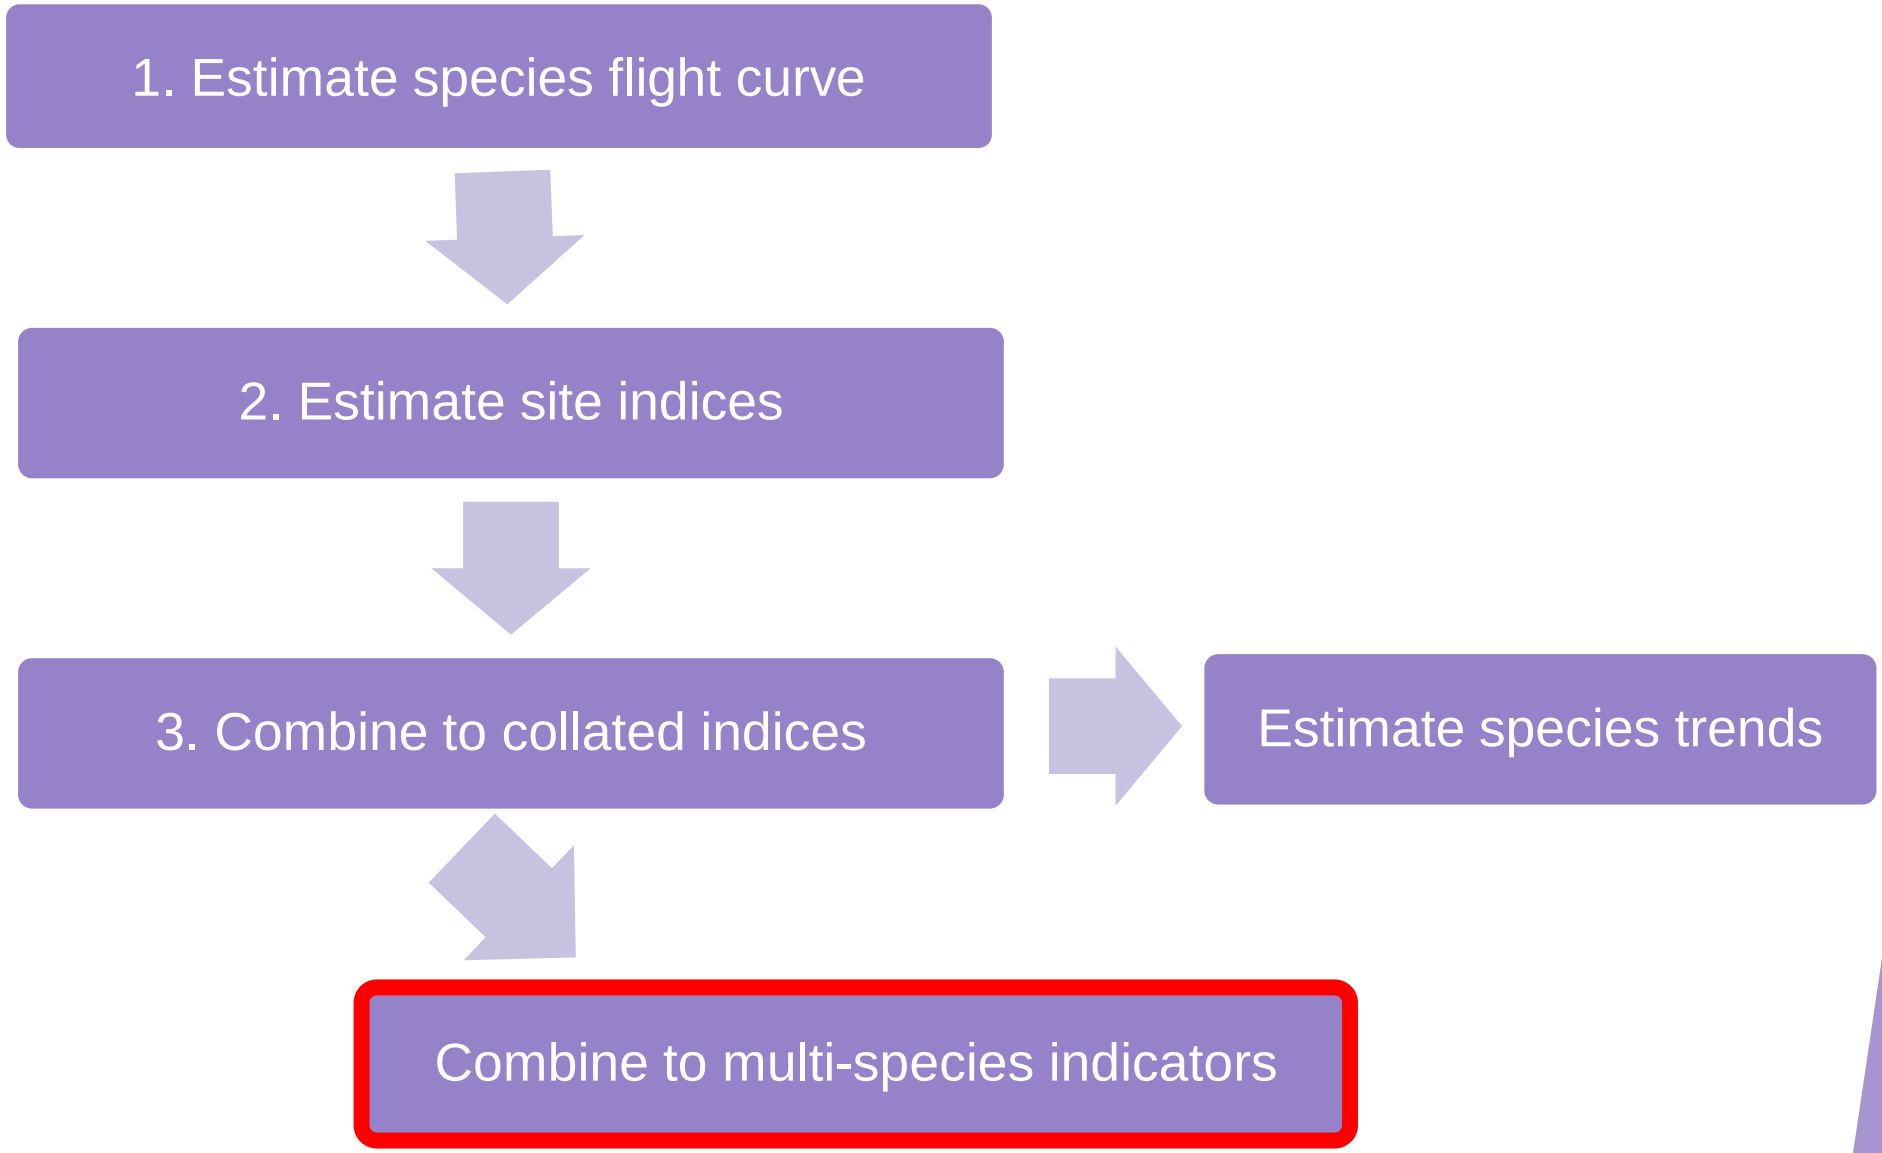
Calculating species trends

Category	Description
Strong increase	Significant increase > 5% per year
Moderate increase	Significant increase but less than 5% per year
Uncertain	No significant change, changes likely to be greater than 5% per year
Stable	No significant change, changes likely to be less than 5% per year
Moderate decline	Significant decrease but less than 5% per year
Strong decline	Significant decrease of >5% per year



Date period	Rate of change	% change	Class
2008-2017	1.032 (1.019, 1.045)	32.5%	Moderate increase

Overview of modelling steps



Multi-species indicators

- Take the geometric mean of the species collated indices
- Common indicator approach e.g. Living Planet Index, bird indices
- The doubling of one species compensates the halving of another species

Species	Year 1	Year 2
A	100	50
B	100	200
Arithmetic mean	100	125
Geometric mean	100	100

Multi-species indicators
